

MESO-MECHANICAL STUDY OF HIGH-TEMPERATURE CRACKING IN MORTAR AND CONCRETE SPECIMENS USING FRACTURE-BASED ZERO-THICKNESS INTERFACES

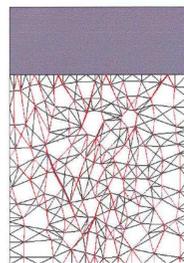

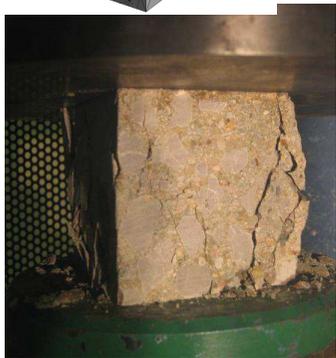

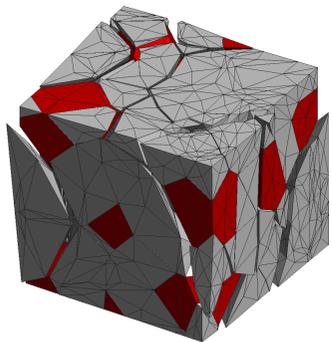

*Mariana Rodríguez
Carlos María López
Ignacio Carol
(ETSECCPB-UPC, Barcelona)*

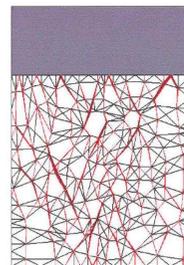

BACKGROUND

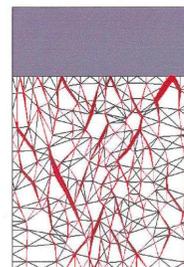

- Mesomechanics of concrete and mortar at cm/mm scale using fracture-based interface elements,
- Extensive verification for cracking-dominated mechanical and as diffusion-driven behavior (drying shrinkage, sulfate attack.)

(a)

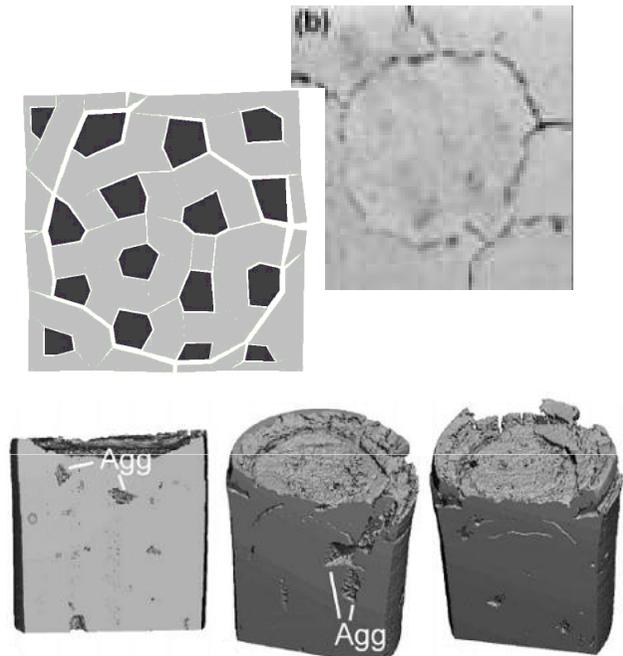

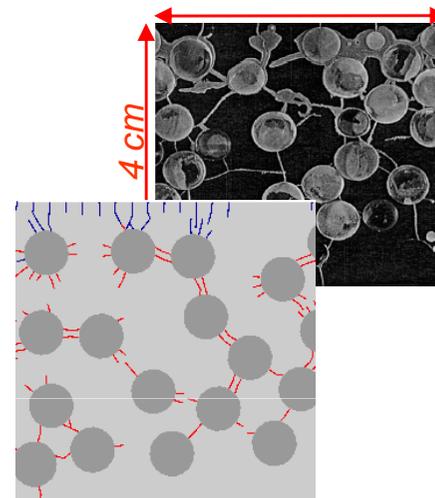

(b)

(c)

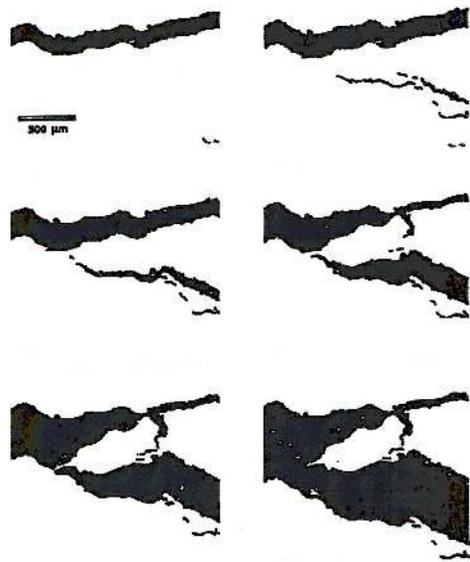

Crack evolution for $\sigma = 31$ MPa, at $t - t' =$ a) 0, b) 100 and c) 10000 days ($t' = 28$ days).

Lopez et al(2000), Lopez and Carol (2001), Roa et al (2001), Caballero et al 2004,2005,2006, 2007), Idiart et al (2010, 2011), Rodriguez et al (2011).

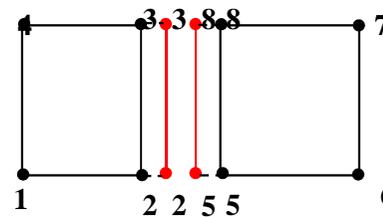

CHARACTERISTIC INGREDIENT: CRACKS via INTERFACE ELEMENTS pre-inserted along FE MESH LINES

Complex physical phenomena:
 (bridging, branching, etc)

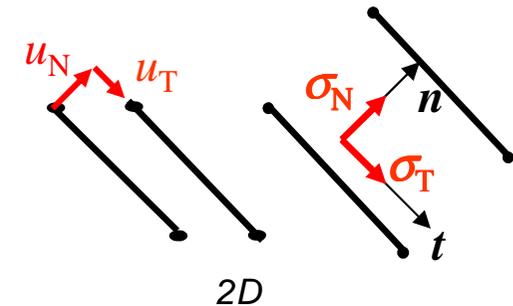

(from *Fracture processes in concrete*, van Mier, 1997)

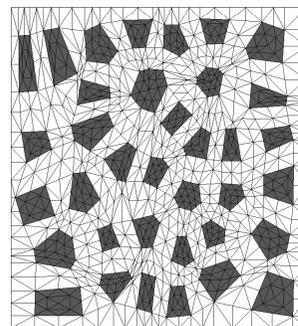

Modeling via zero-thickness interface elements

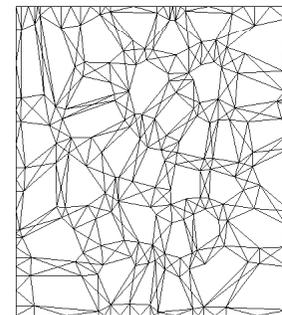

Insertion between standard FE

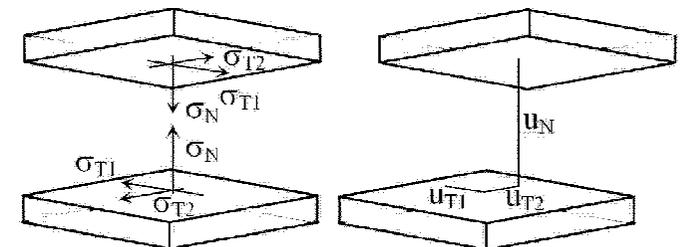

Constitutive variables

Interface elements

INTERFACE CONSTITUTIVE MODEL

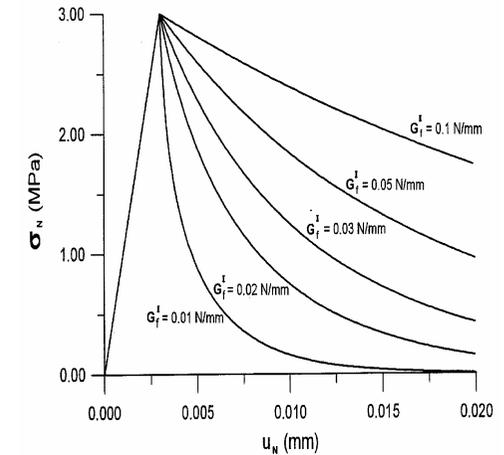

(Carol, Prat, Lopez, JEM 1997... Caballero, Willam, Carol CMAME 2008)

Within Elasto-Plastic framework

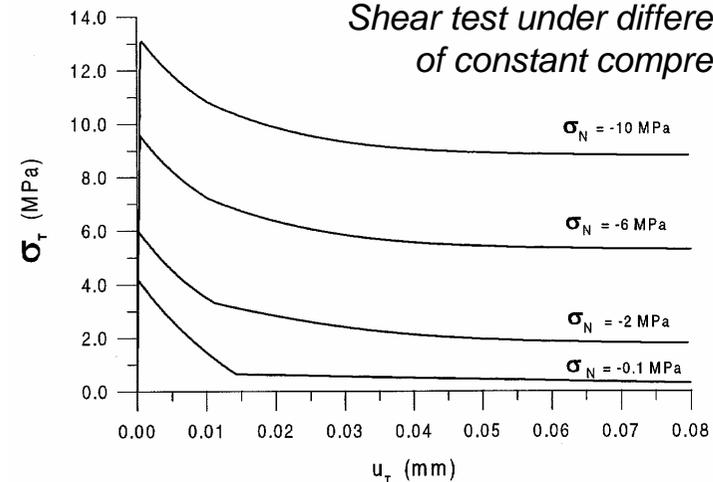

Resulting interface behavior

Pure tensile behavior

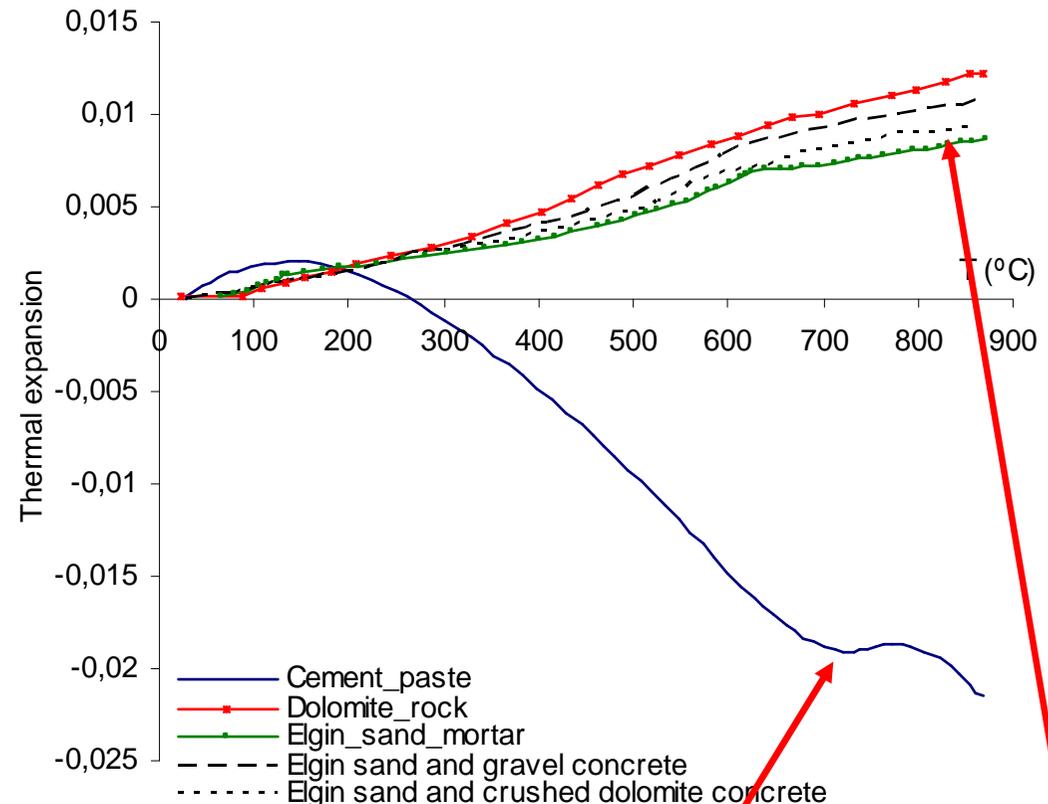

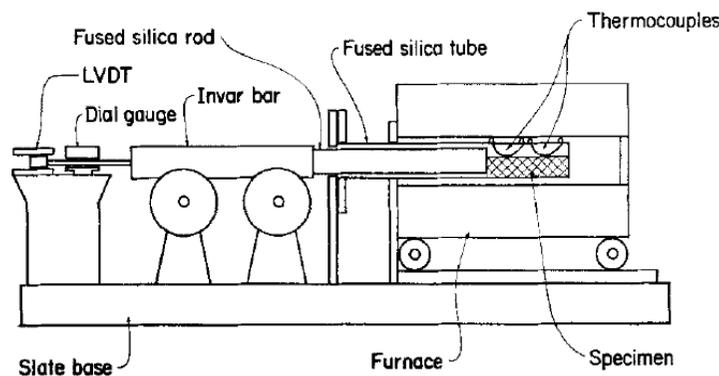

Shear test under different values of constant compression

- Static Variables: normal and tangential stresses σ_N, τ
- Kinematic variables: normal and tangential relative displacements
- Hyperbolic fracture surface
- Associated flow in tension, dilatancy reduced in compression
- Work-softening in terms of W^{cr} , with parameters G_f^I and G_f^{IIa}

Motivation: EXPERIMENTS BY CRUZ AND GUILLEN (1980)

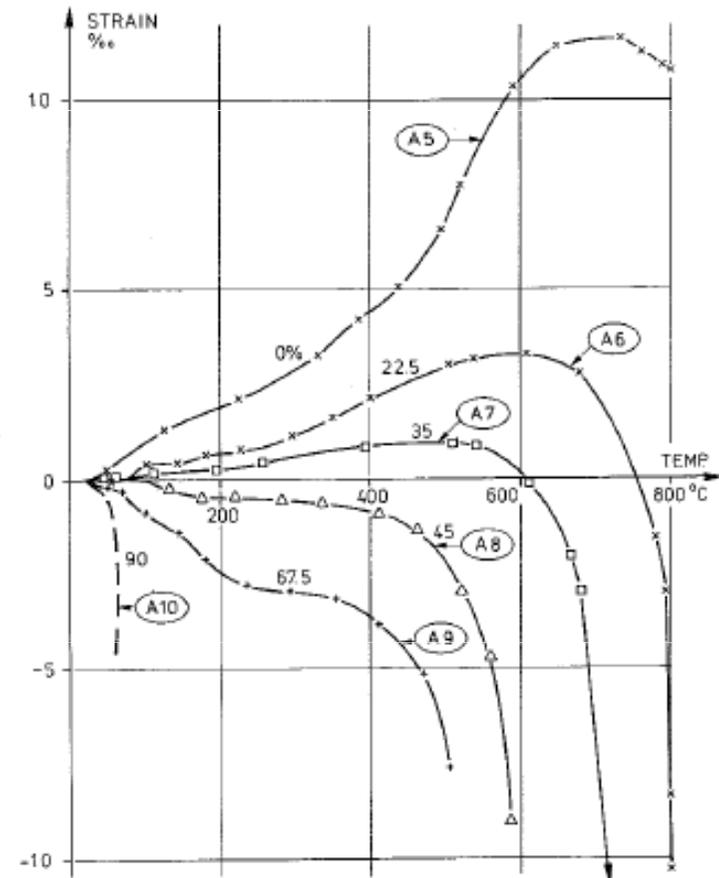

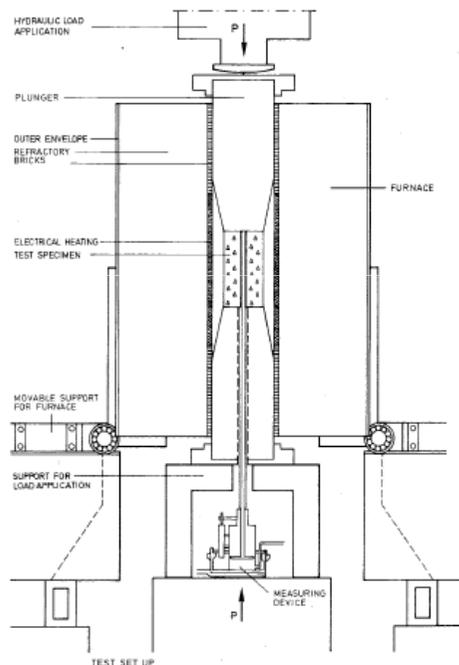

- FREE EXPANSION of cement, rock, concrete and mortar specimens
- Small cylindrical specimens 13mm in diameter and 76mm in length (uniform temp assumed !)
- Purely mechanical approach (no consideration of diffusion/flow)
- Temperature range: 27 – 871°C

CONTRACTION
 of cement paste.... but **OVERALL**
EXPANSION due
 to cracking !

Motivation (cont): EXPERIMENTS BY ANDERBERG AND THELANDERSSON 1976 (“LITS effect”)

- EXPANSION UNDER CONSTANT STRESS of concrete specimens
- Cylindrical samples 75mm in diameter and 150mm in length
- Purely mechanical approach (no explicit consideration of diffusion/flow)
- Temperature range: 20 – 800°C

NO SUPERPOSITION PRINCIPLE between applied stress and ΔT !

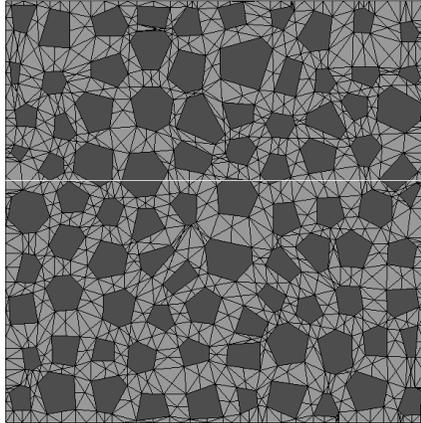

MAIN OBJECTIVES OF THIS STUDY

- General: To extend the existing meso-model to represent high temp effects.
- Initially, consider only mechanical effects of differential expansions, taking as input data the expansion curves by Cruz and Guillen and uniform temp.
- Consider interaction with loadign, see the resulting combined effect on cracking, deformations, comparison to LITS (uniform temp.)
- Consider transient temp, ISO Curve, spalling.

OUTLINE

- Introduction (background, motivation, objectives..)
- Application of the numerical model to the basic known cases
- Numerical simulations of spalling of wall subject to heating.
- Concluding remarks

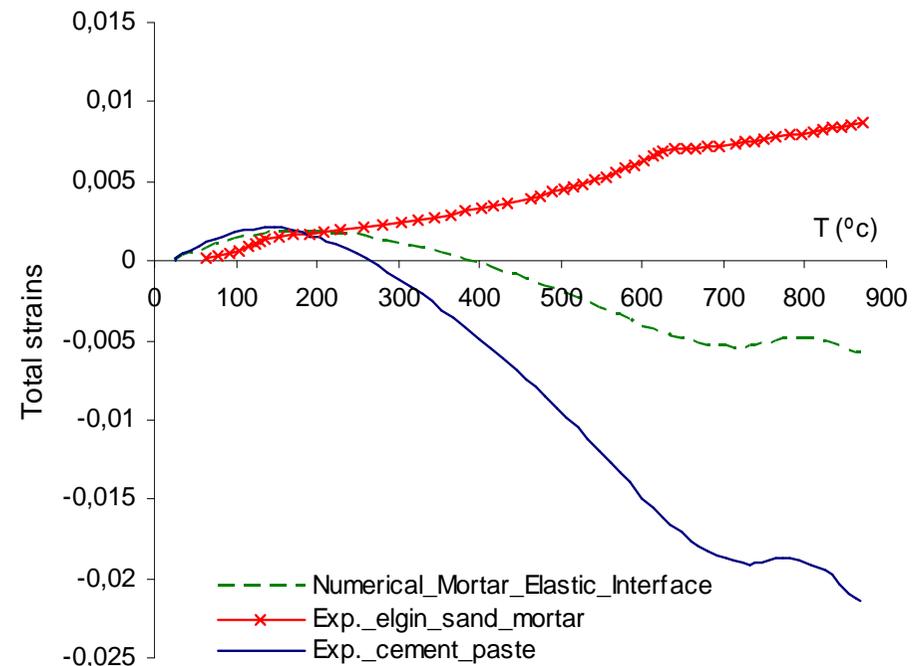

NUMERICAL RESULTS FOR FREE EXPANSION OF MORTAR, UNIFORM TEMP.

- Two-phase composite
- Cement paste with a variable coefficient of thermal expansion, extracted from the experimental cement paste curve.
- Sand with a constant coefficient of thermal expansion
- 12x12 mm square specimens
- Volume fraction of sand: 39%
- Maximum size aggregate: 1.7mm

➤ Preliminary Elastic analysis

- Interfaces are not allowed to open or slide
- The changes of expansion to contraction is delayed.

NUMERICAL RESULTS FOR FREE EXPANSION OF MORTAR, UNIFORM TEMP.(2)

➤ Non-linear analysis with cracking

- Interface elements allowed to open/slide if cracking conditions are reached (constitutive model)

Interface constitutive parameters:

$E = 70000$ MPa (dolomite rock)

$E = 25000$ MPa (cement paste)
 and $\nu = 0.2$ (both).

All interfaces:

$K_N = K_T = 500000$ MPa/mm

$\tan\phi_0 = 0.90$

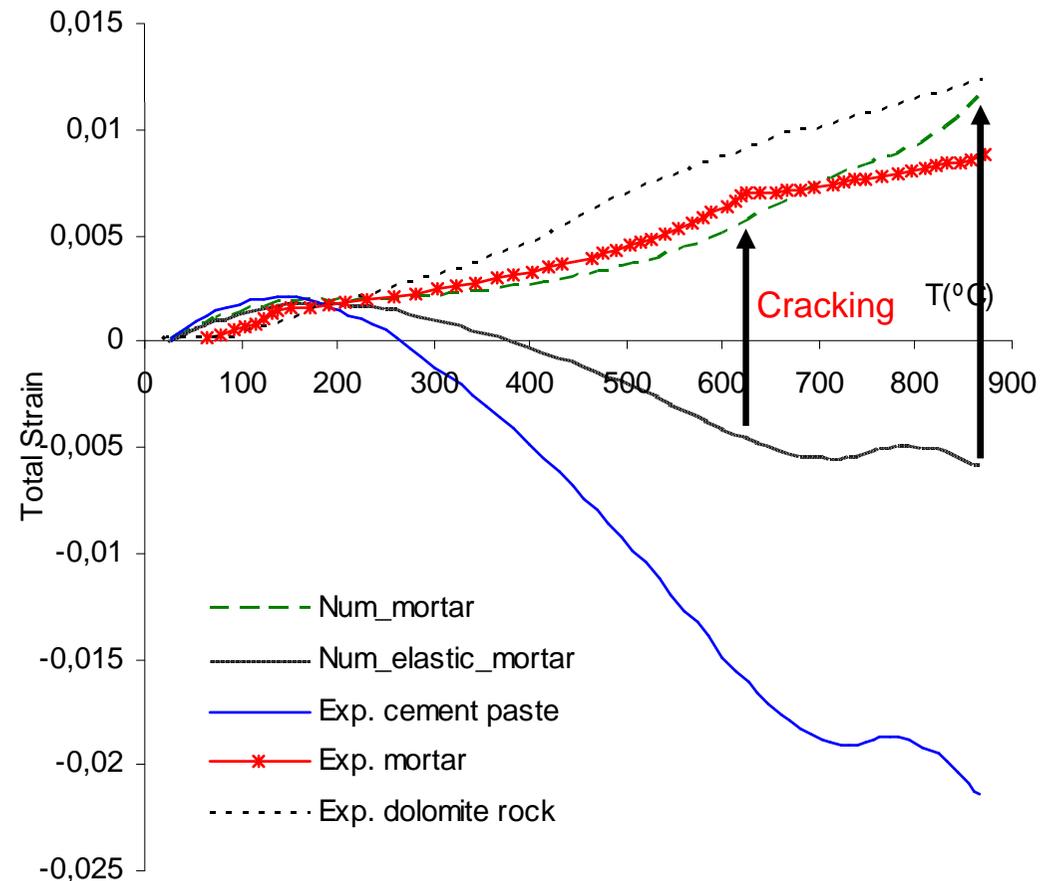

$\chi_0 = 6$ MPa

$c_0 = 15$ MPa

$G_I^F = 0.025$ N.mm, $G_{II}^F = 10G_I^F$

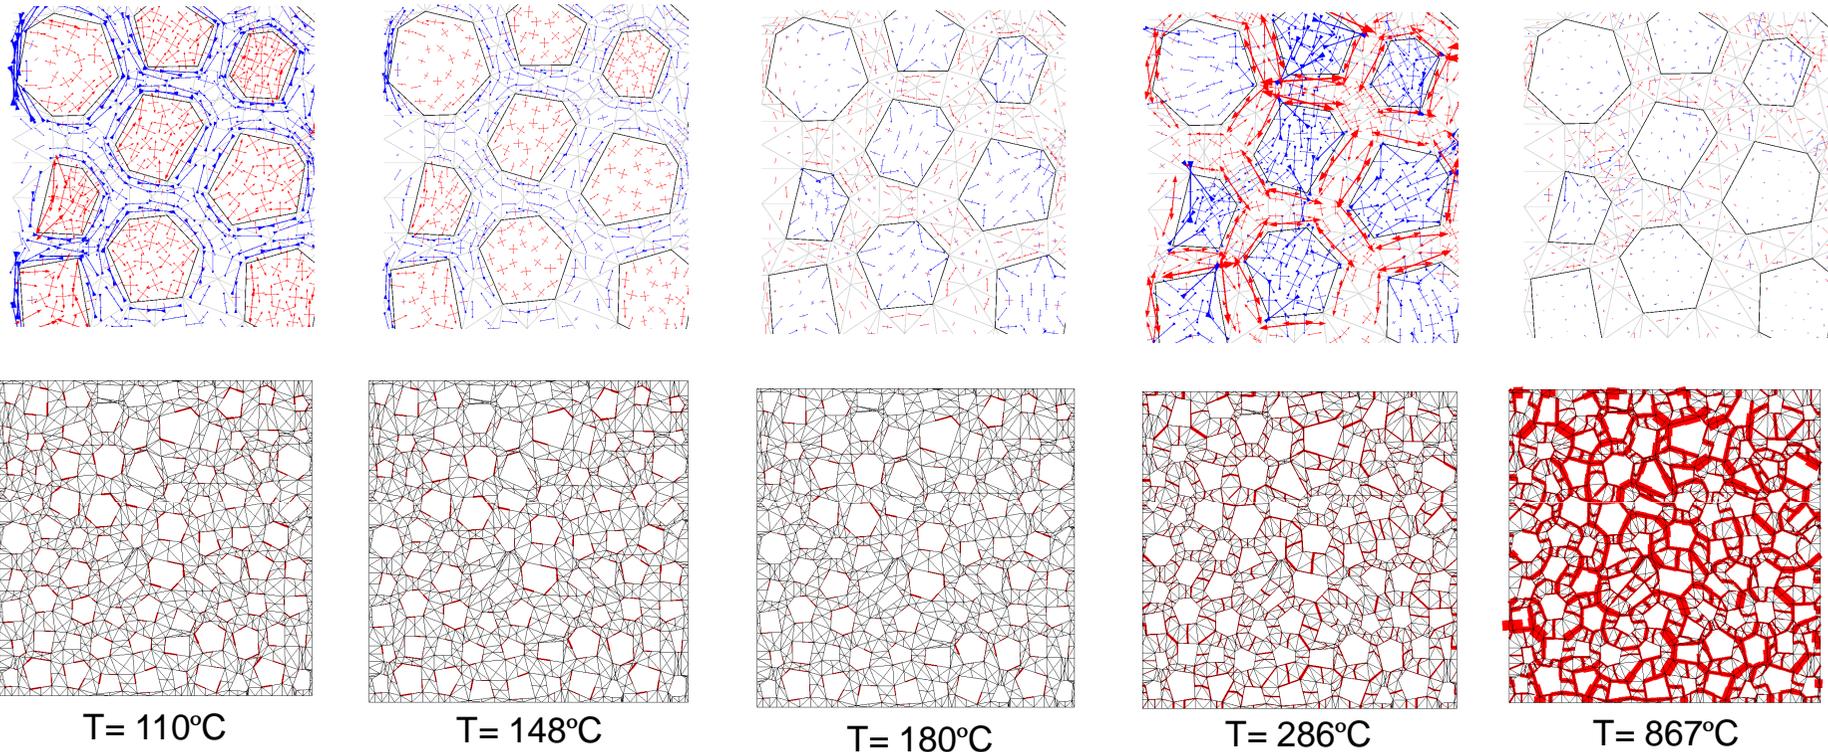

$\sigma_{dil} = 40$ MPa

$\alpha_d = -2$.

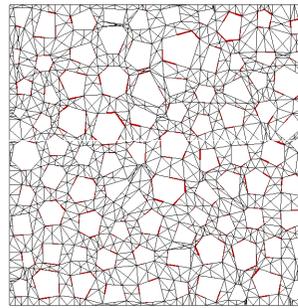

NUMERICAL RESULTS FOR FREE EXPANSION OF MORTAR, UNIFORM TEMP.(3)

Evolution of continuum stresses and crack opening

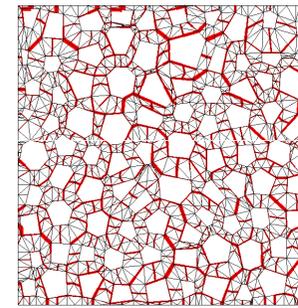

NUMERICAL RESULTS FOR FREE EXPANSION OF CONCRETE, UNIFORM TEMP.

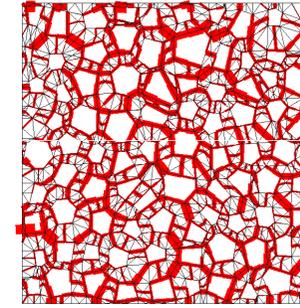

- Two-phase composite
- Mortar with a variable coefficient of thermal expansion extracted from numerical mortar curve.
- Large aggregates with a constant coefficient of thermal expansion
- 10x10 cm square specimens
- Volume fraction of sand: 28%
- Maximum aggregate size: 14mm

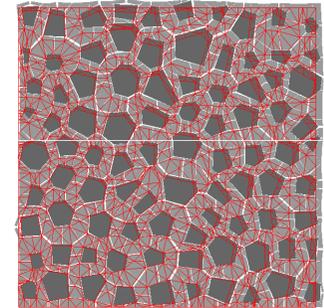

T=157°C

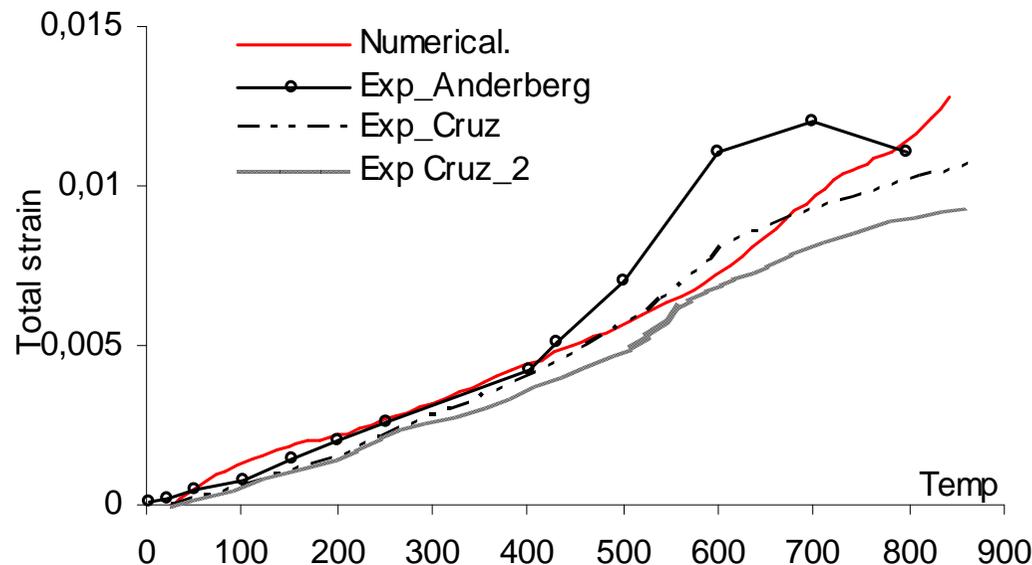

T=519°C

T=867°C

T=867°C

Material parameters:

$E = 70000$ MPa (dolomite rock)

$E = 29000$ MPa (mortar) and $\nu = 0.2$ (both).

Aggregate-mortar interfaces: Mortar-mortar interfaces:

$K_N = K_T = 500000$ MPa/mm

$K_N = K_T = 500000$

$\tan\phi_0 = 0.90$

$\tan\phi_0 = 0.90$

$\chi_0 = 4$ MPa

$\chi_0 = 6$ MPa

$c_0 = 15$ MPa

$c_0 = 20$ MPa

$G^F_I = 0.025$ N.mm, $G^F_{II} = 10G^F_I$

$G^F_{II} = 10G^F_I$

$G^F_I = 0.030$ N.mm,

$\sigma_{dil} = 40$ MPa

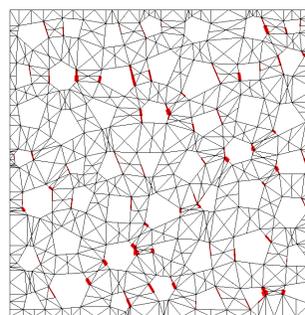

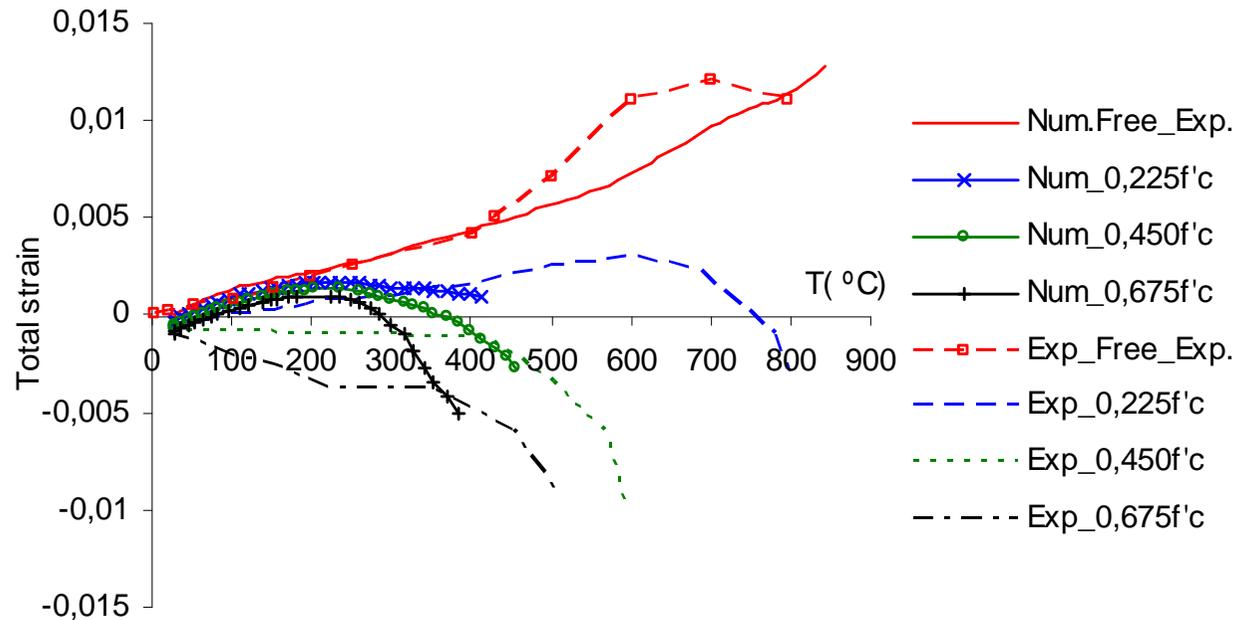

$\sigma_{dil} = 40$ MPa

$\alpha_d = -2$

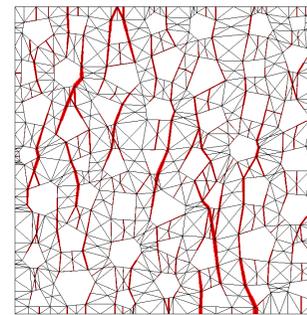

$\alpha_d = -2$

THERMAL EXPANSION OF CONCRETE UNDER UNIFORM TEMP + APPLIED STRESS (LITS EFFECT)

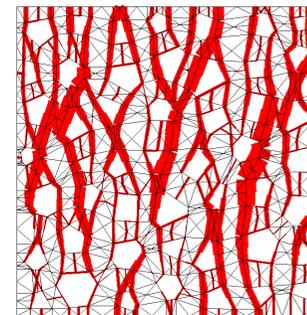

- The specimens were loading to a certain vertical stress level and then heated to 800°C
- The stress level is given as a percentage of compressive strength of the material
- Three cases were analyzed
- Experimental curves were moved to the origin after the pre-compression (as it was done in exp. curves)

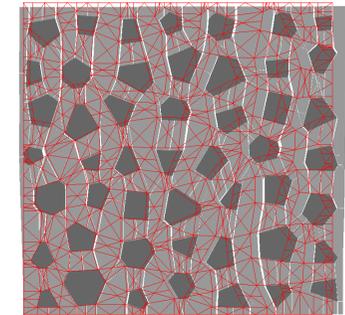

T = 157°C

T = 352°C

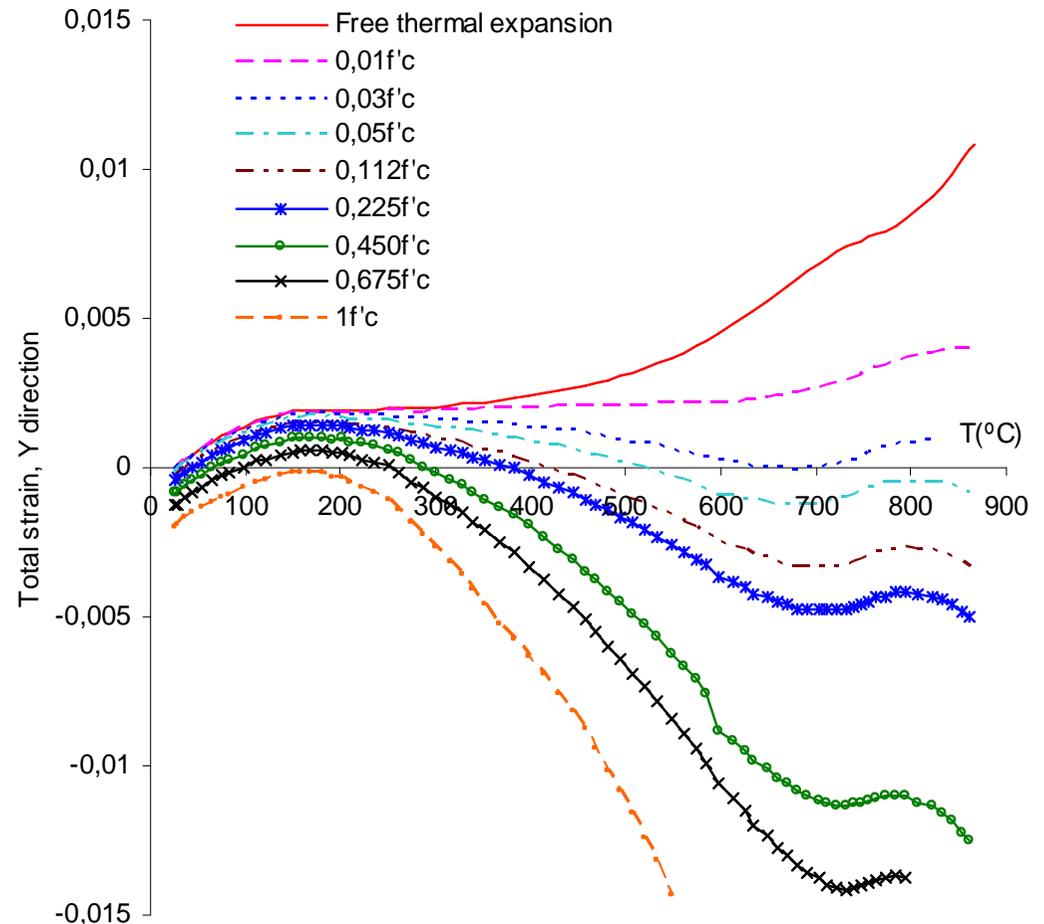

T = 494°C

T = 494°C

EXPANSION OF MORTAR UNDER UNIFORM TEMP+APPLIED STRESS **(numerical only)**

- The mesh used is the same as the one used for previous mortar analysis
- Ten cases were analyzed
- Experimental curves were not corrected to the origin
- The effect of compression is reflected by the shift downwards of each curve (not moved here)
- For $T < 200$ °C aprox, both effects loading and thermal, could be simply superimposed
- For higher temperature, the curves tend to follow the matrix compression, cracking and overall deformation are delayed

TIME-DEPENDENT IMPOSED TEMPERATURE VALUES on boundary (ISO 834), TRANSIENT THERMAL ANALYSIS ON THE SAME MESH

$$T = 345 \text{Log}_{10}(8t + 1) + 20$$

Thermal parameters		
	Mortar	Aggregate
Thermal conductivity [J/min cm °C]	0,66	1,1
Density [Kg/cm3]	0,0023	0,0026
Specific heat [J/Kg°C]	1,17E+03	7,11E+02
Difussivity [cm2/min]	0,24	0,60
Thermal Expansion coeff. [1/°C]	variable	cte. = 0,0000125

Material parameters:

E = 70000 MPa (aggregate)
 E = 29000 MPa (cement paste)
 and $\nu = 0.2$ (both).

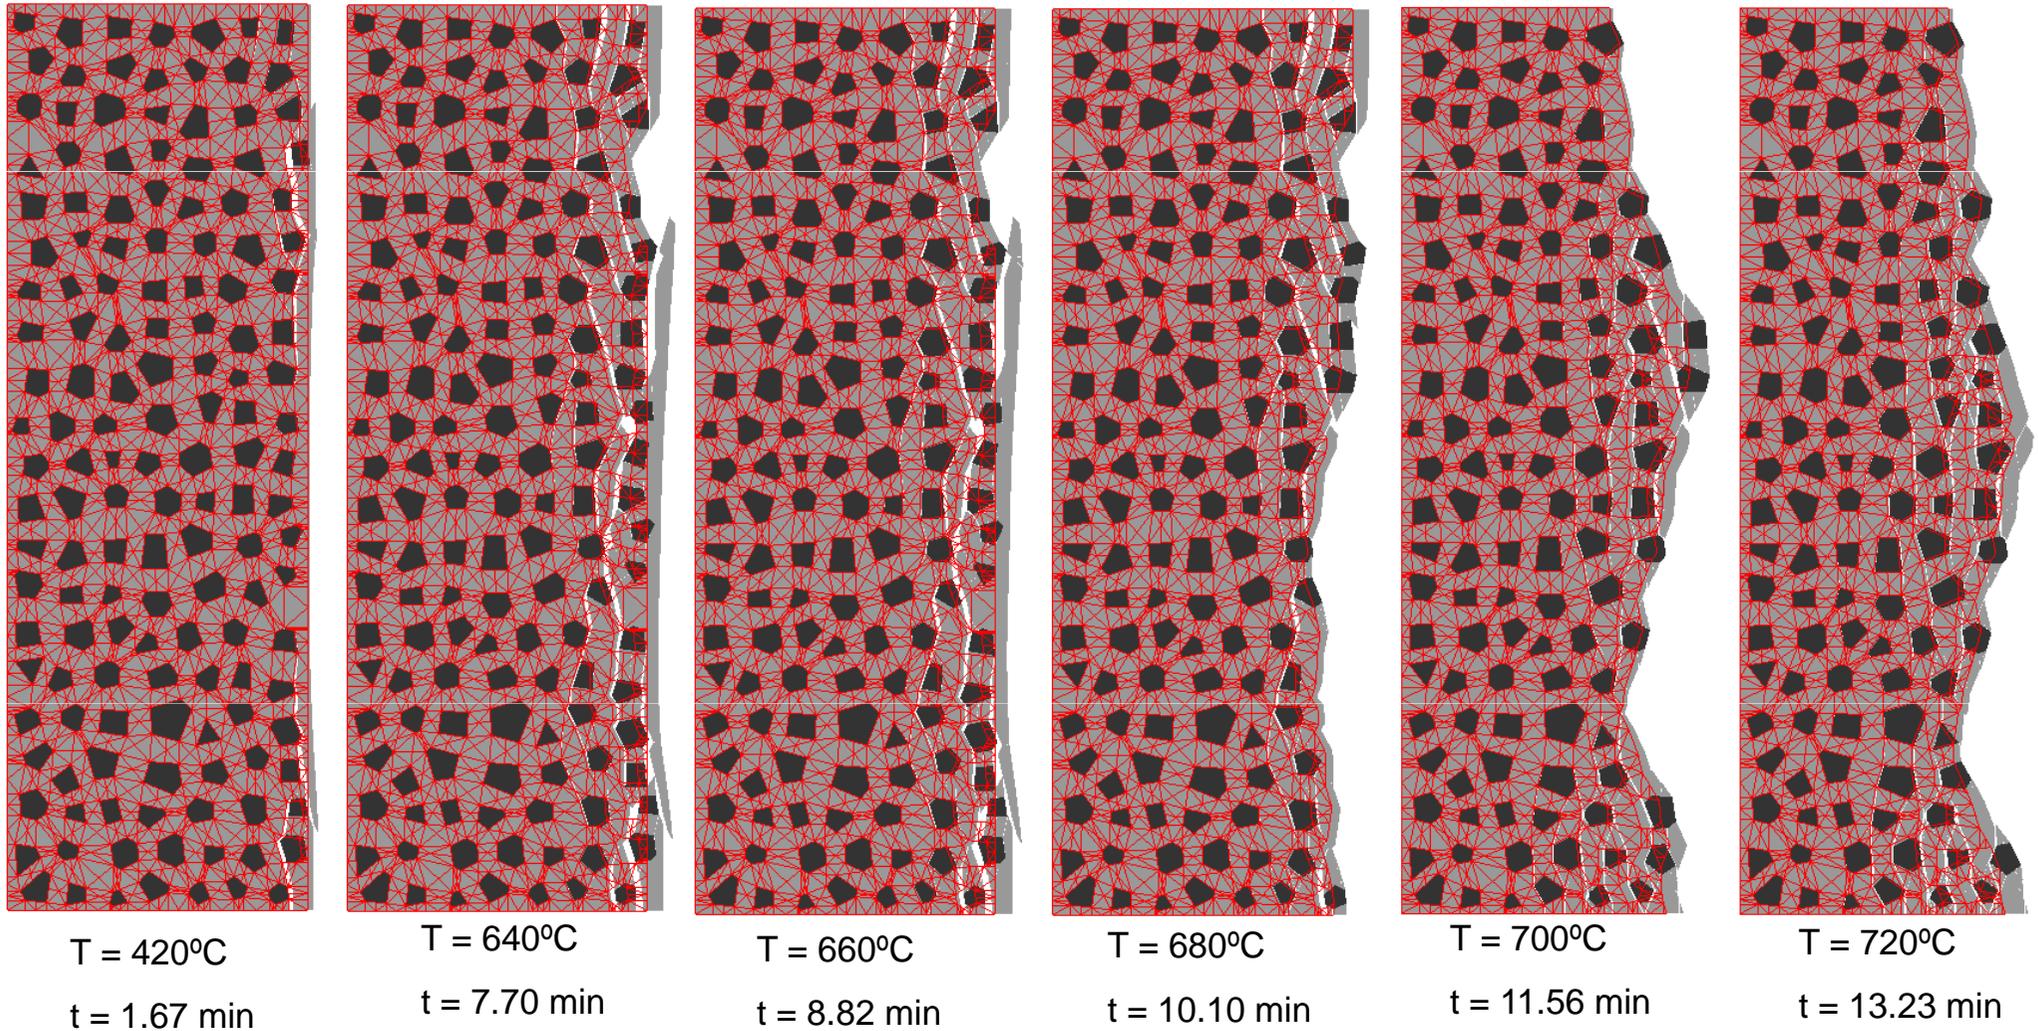

Aggregate-cement paste interfaces:

$K_N = K_T = 500000$ MPa/mm
 $\tan\phi_0 = 0.90$
 $\chi_0 = 4$ MPa
 $c_0 = 15$ MPa
 $G^F_I = 0.03$ N.mm, $G^F_{II} = 10G^F_I$
 $\sigma_{dil} = 40$ MPa
 $\alpha_d = -2$.

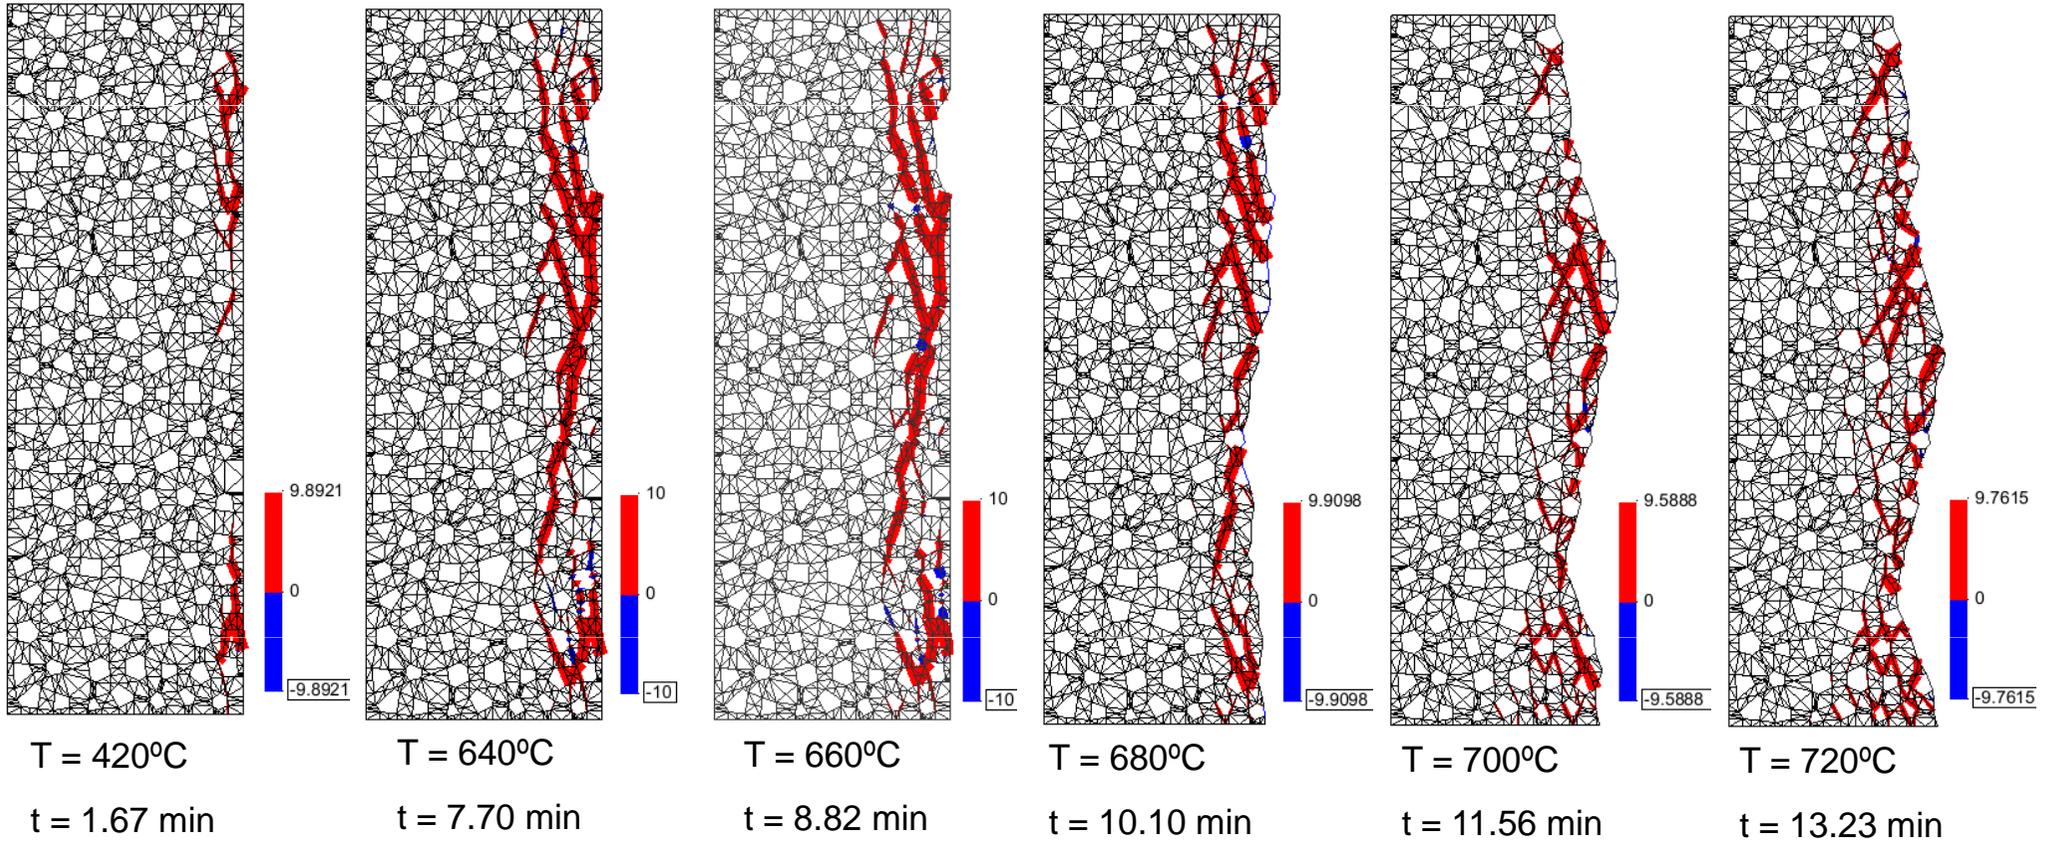

Cement-cement interfaces:

$K_N = K_T = 500000$ MPa/mm
 $\tan\phi_0 = 0.90$
 $\chi_0 = 6$ MPa
 $c_0 = 22.5$ MPa
 $G^F_I = 0.06$ N.mm, $G^F_{II} = 10G^F_I$
 $\sigma_{dil} = 40$ MPa
 $\alpha_d = -2$.

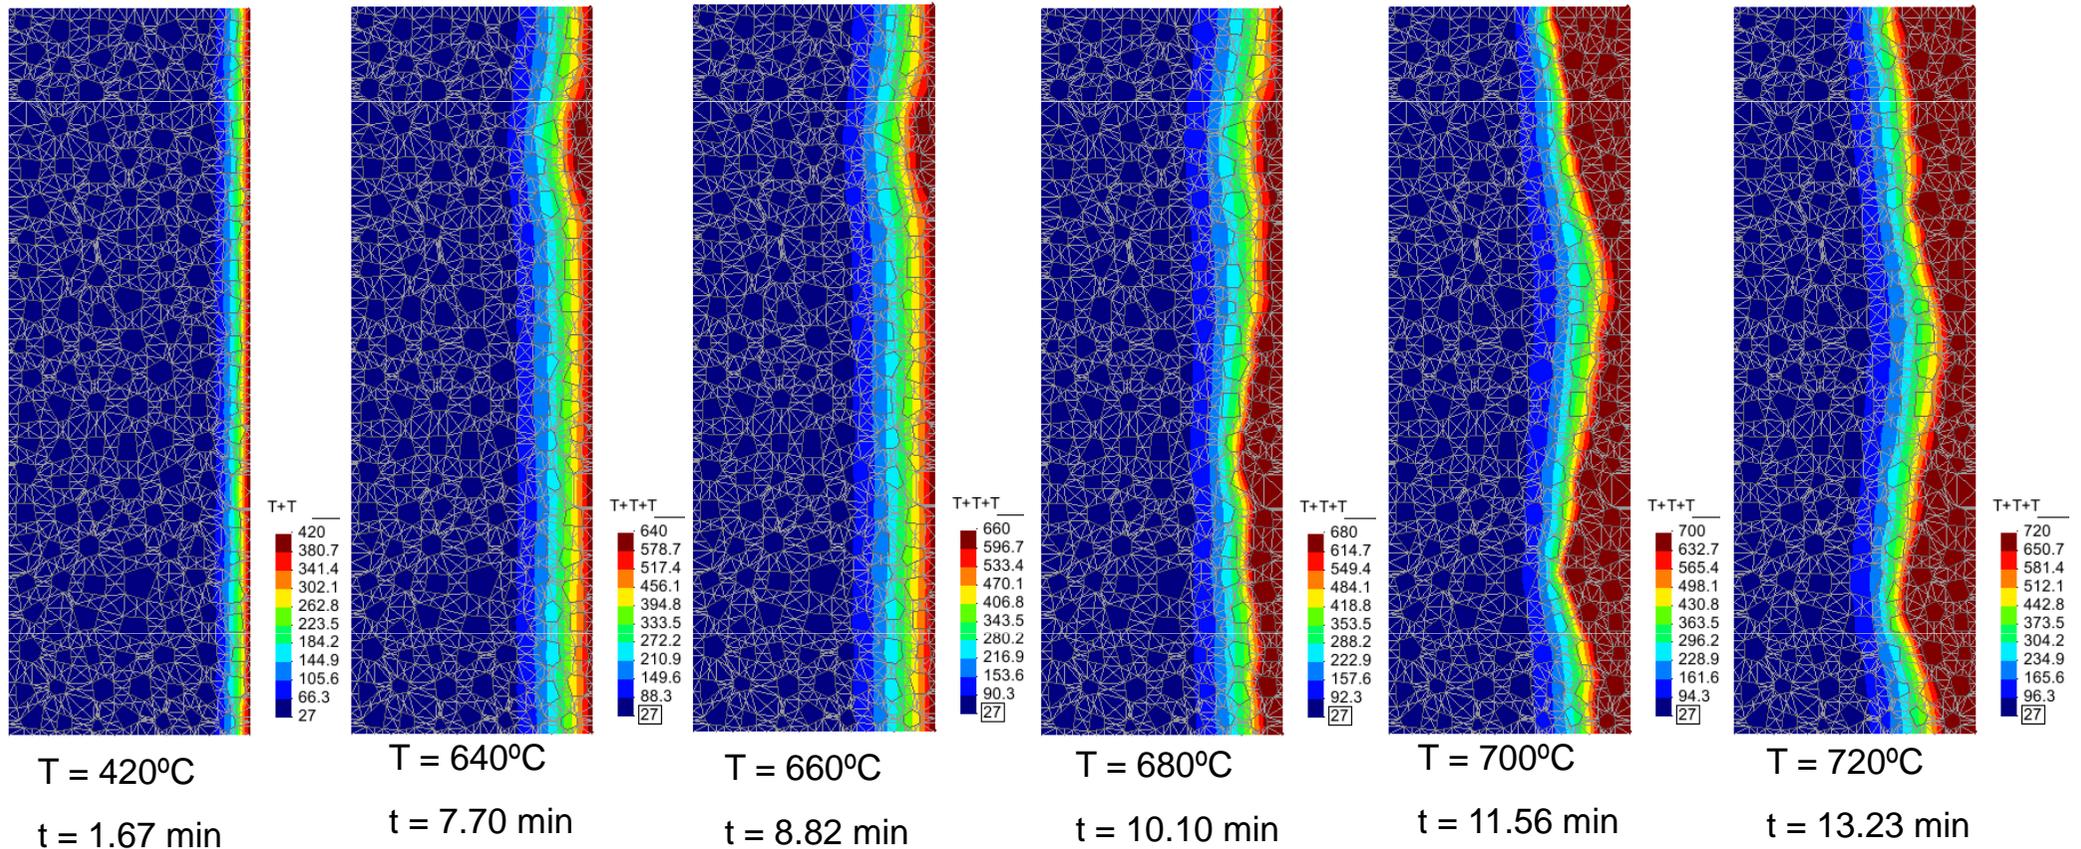

EVOLUTION OF CRACKING, ELEMENT REMOVAL AFTER $W_{cr}=G_f^I$

TIME-DEPENDENT IMPOSED TEMPERATURE VALUES (ISO 834), APPLIED ON SPALLED SURFACE(!)

CONCLUDING REMARKS

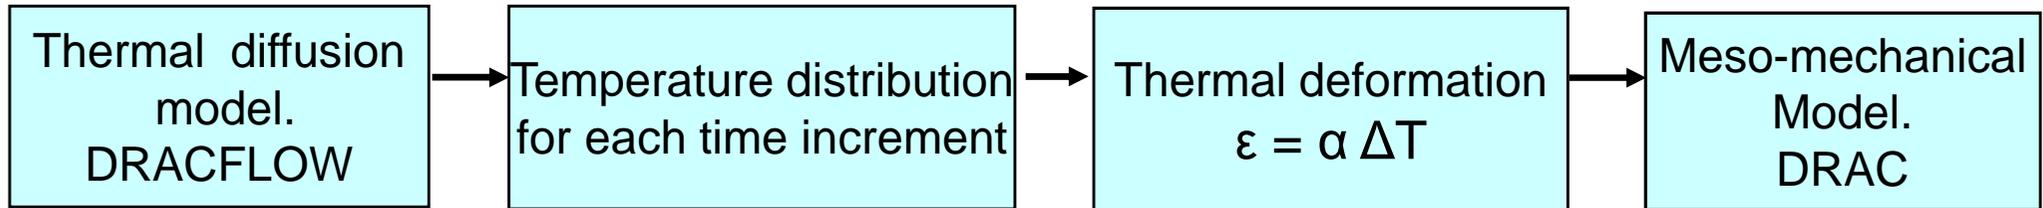

- In spite of simplistic assumptions, the meso-model seems to capture the main trends of classical high temperature experimental observations on concrete and mortar.
- Free expansion tests are dominated by the expanding aggregates, while in pre-compressed tests cracking perpendicular to the stress is reduced or prevented altogether, leading to LITS.
- Removal of concrete pieces leads to clear spalling, progressing into specimen.
- Updating Temp. B.C to spalled surface actually introduces T-M COUPLING. However, effect may be too drastic, since spalling does not stop, eventually erodes totally the cross-section. In reality probably pieces stay, slows down BC penetration.
- On-going work aims at combining this purely mechanical description with a diffusion model for the heat transfer and humidity migration within cement paste,
- ...as well as 3D extension.

Thanks for your Attention!

NON-UNIFORM TEMPERATURE DISTRIBUTION ANALYSIS

- The mesh used is the same as the one used for previous mortar and concrete analysis.

-The same expansion .vs. temperature law that in previous mortar and concrete uniform temperature are used.

- Thermal parameters are the same for concrete and mortar.

-An imposed temperature value of 400°C is applied on the four faces of the specimens.

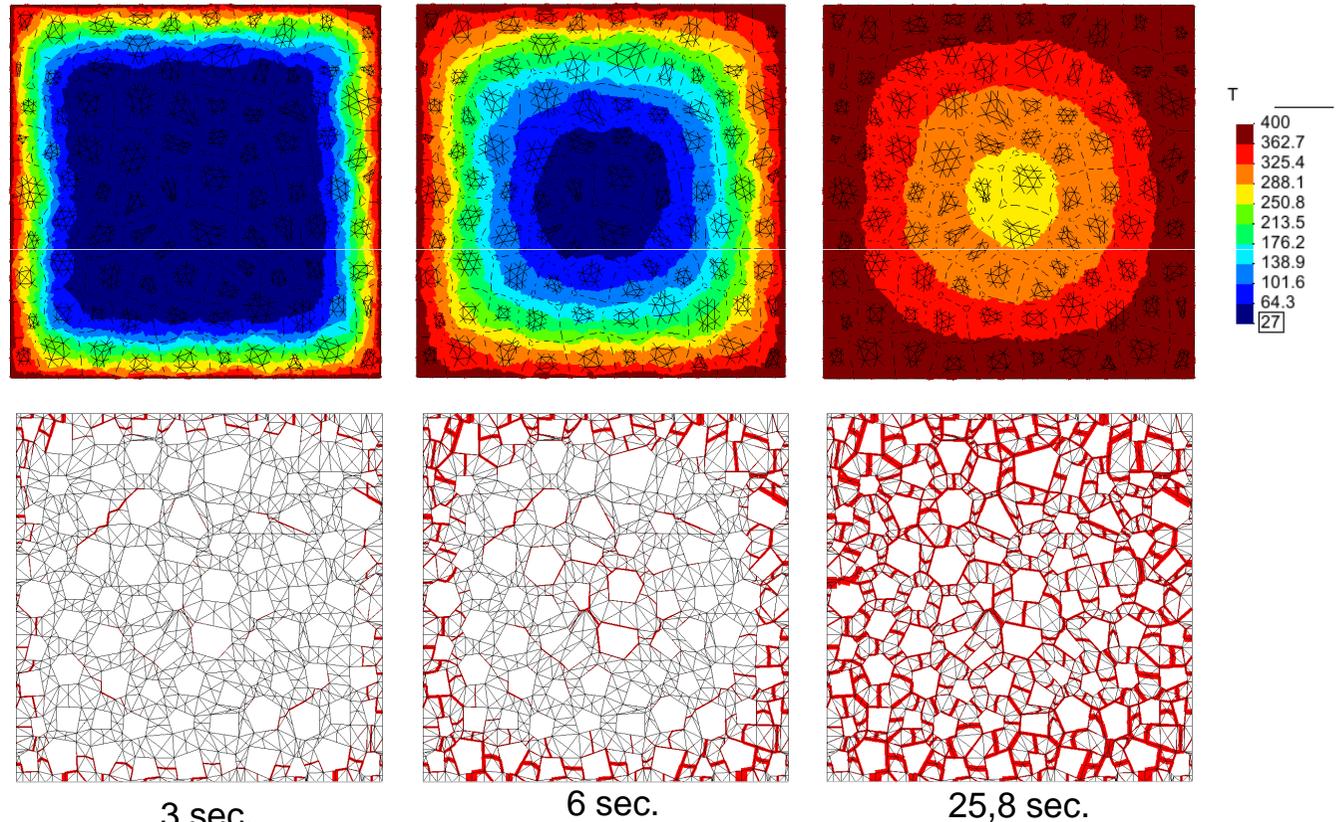

Thermal parameters		
	Mortar	Aggregate
Thermal conductivity [J/min cm °C]	0,84	1,44
Density [Kg/cm ³]	0,0023	0,0026
Specific heat [J/Kg°C]	1,17E+03	7,11E+02
Difussivity [cm ² /min]	0,31	0,77
Thermal Expansion coeff. [1/°C]	variable	cte. = 0,0000125

MORTAR SPECIMEN, FREE THERMAL EXPANSION (presc.fixedTemp on boundary)

- The temperature fronts move toward the center of the specimens in a not perfectly uniform manner due to the different diffusion coefficient for the two phases.

- In correspondence with the temperature changes, some microcracking is generated.

-Microcracking starts on the specimens surface and propagates inward until it becomes more or less uniform.

Material parameters:

$E = 70000$ MPa (dolomite rock)
 $E = 25000$ MPa (cement paste)
 and $\nu = 0.2$ (both).

Dolomite sand-cement interfaces:

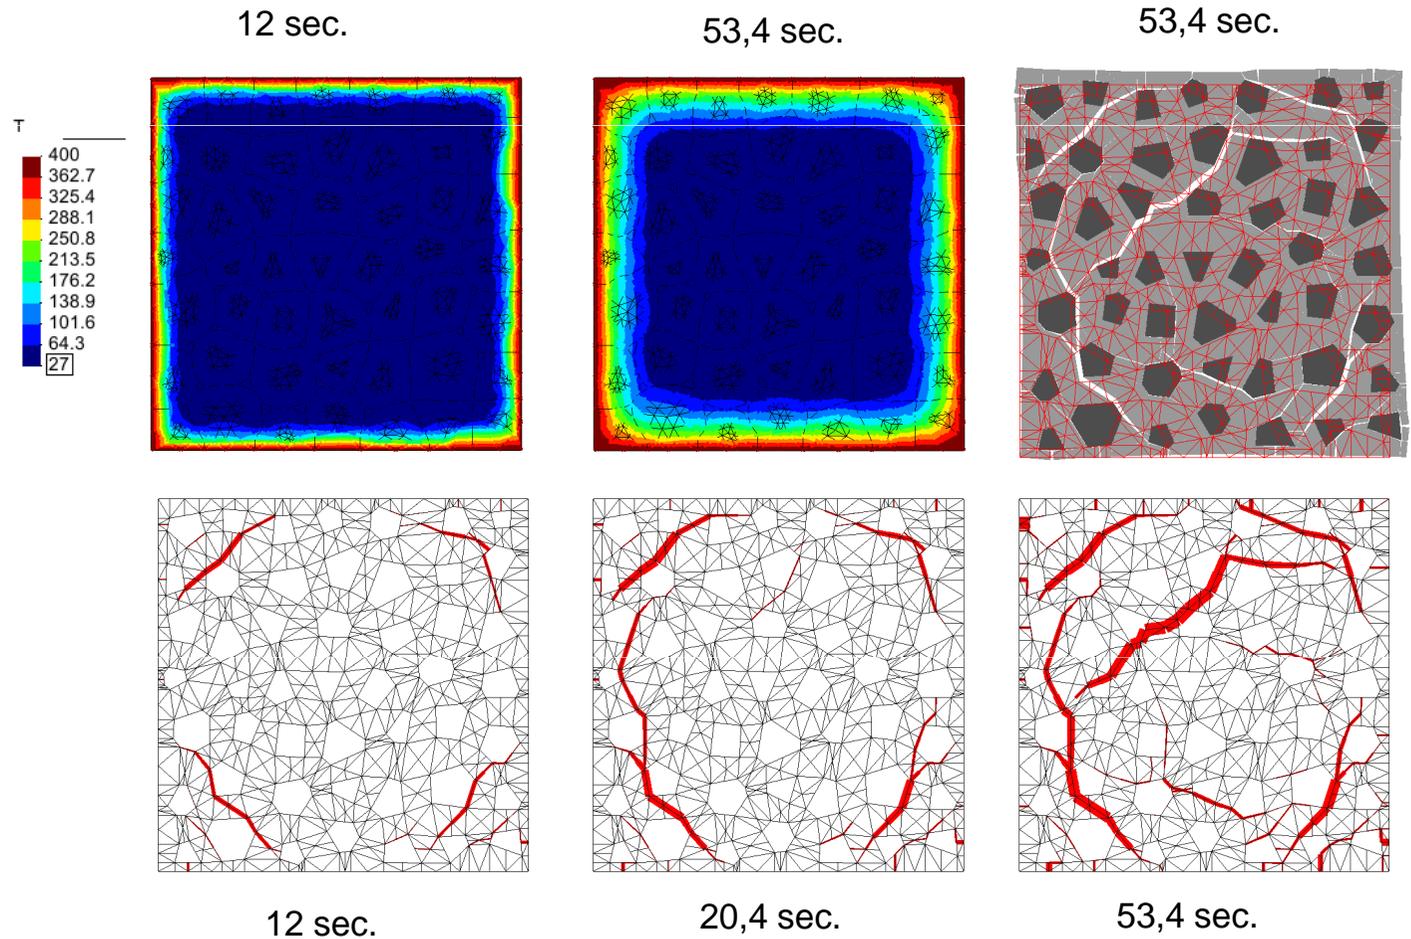

$K_N = K_T = 500000$ MPa/mm
 $\tan\phi_0 = 0.90$
 $\chi_0 = 3$ MPa
 $c_0 = 7,5$ MPa
 $G_I^F = 0.03$ N.mm, $G_{II}^F = 10G_I^F$
 $\sigma_{dil} = 40$ MPa
 $\alpha_d = -2$.

Cement-cement interfaces:

$K_N = K_T = 500000$ MPa/mm
 $\tan\phi_0 = 0.90$
 $\chi_0 = 6$ MPa
 $c_0 = 15$ MPa
 $G_I^F = 0.06$ N.mm, $G_{II}^F = 10G_I^F$
 $\sigma_{dil} = 40$ MPa
 $\alpha_d = -2$.

CONCRETE SPECIMEN, FREE THERMAL EXPANSION

- The same mechanical parameters as in previous cases are used
- Cracks start at the corners of specimens along aggregate-matrix contacts, and they develop a perimeter crack (spalling).
- For higher temperature values, additional cracks form in the center of the specimen.
